Linea

By Branson Wu

I wish I knew how this text would come across before I sent it!

I wish my messages sounded more like me, just clearer.

Why did I come across so mean?

Oops, should not have said that!

For the messages and decisions that matter most

Idea Overview

Linea is an AI tool that analyzes a message draft by the user, then gives a forensic analysis of the message. This includes breaking down the message into layers: literal meaning, implied assumptions and likely ways it could be interpreted, emotional tone, and highlighted triggers, and suggestions on ways the user could take the direction of this text.

After that, it gives the user suggestions on how the message can be changed based on the emotion they want to convey and the intent of the message. It may also ask clarifying questions to generate stronger suggestions.

Ethical Considerations

This app is designed so that users do not upload or edit the other person's private texts. Instead, the system only uses the user's own drafted message, their description of the situation, and examples/uploads of their own past writing style. That keeps the tool focused on helping users communicate more clearly in their own voice, rather than analyzing or manipulating someone else's private data without consent.

Let Linea Improve Your Messaging

Relevance to Creativity and AI

11:25 AM

Relevance

Linea does not generate a replacement text or give general advice and forensic analyst, instead it is a more detailed communication editor.

This project connects to creativity and AI because it helps users express themselves in clearer and more thoughtful ways. AI analyzes tone and the writing style, then helps give suggestions while keeping the user's own voice.

12:45 PM

Unique Point

A really strong addition is letting users upload or paste in their own past messages so the model can learn their tone, rhythm, vocabulary, and texting habits.There will be a saved database of all these messages as well as any important notes that the user inputs.

Then when linea rewrites something, it can sound more like the user instead of sounding generic or robotic.

Target Use

01 Personal Relationships

Helps users draft thoughtful messages for emotionally important conversations with friends, family, or partners.

02 Conflict Resolution

Supports users in rewriting tense messages so they sound clearer, calmer, and less likely to be misunderstood.

03 Professional/Corporate

Improves emails, Slack messages, and workplace communication by making tone more polished, tactful, and intentional.

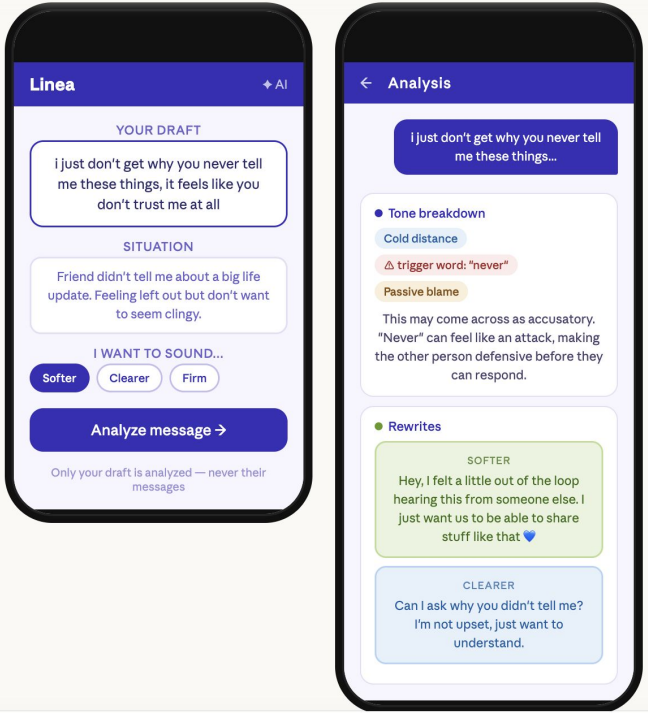
04 Self-Expression

Uses the user's own writing style to help them say what they mean more clearly without sounding robotic or unlike themselves.

Design & Development

- **Start with the core workflow**
  First, I would build the main experience of the app: the user enters a draft message, gives a short explanation of the situation, and chooses the tone they want. The app would then return analysis and a few rewritten versions.
- **Build the interface and backend together**
  I would create a simple app with screens for input with screens for input and results, then connect that to a backend that handles and connects all the AI.
- **Add the AI analysis and rewrite features**
  The AI system would first analyze the draft for tone, possible triggers, and likely interpretation, then generate revised versions such as clearer, softer, or more professional rewrites.
- **Add style personalization**
  After the main system works, I would refine the feature where users can upload examples of their own past writing so the rewrites sound more natural and more like them.

← Prototype



Finally, I would try the app on different kinds of messages and see whether the outputs feel accurate, helpful, and authentic. Then I would refine the prompts and interface based on what works best.

AI/ML Needs

This is the main model that reads the user's draft, understands tone and context, and rewrites the message based on the emotion or style the user wants.

This is used to turn the user's past writing into embeddings so the app can learn their voice and pull similar examples from how they normally write.

This is a smaller, faster embedding model used for quick similarity matching, like comparing the current draft to past messages with similar wording or tone.

GPT-5.4 is strong at understanding and rewriting, while voyage-4-large and MiniLM are better for style matching and retrieval. Together, they make the app both smarter and more personalized than using just one model alone.

Foreseen Challenges

Accurately matching the user's real writing style

The app needs to make rewrites sound natural and personal, not like generic AI. Capturing things like humor, slang, directness, and pacing from limited writing samples will be difficult.

Separating tone from actual intent

A message may come across as cold, defensive, or too intense even if that is not what the user means. The challenge is helping users see that gap clearly without oversimplifying the situation.

Balancing personalization with privacy

The app depends on past writing samples, but it also needs strong limits on what can be uploaded. Keeping the system useful while protecting privacy and avoiding third-party data is a major challenge.

Handling different contexts correctly

A good rewrite depends on who the message is for and what kind of situation it is. The app needs to adjust well across personal and professional contexts so the suggestions actually fit.

Thank You!
